# **BHTOM-SPEC**

*Release 0.0.1*

**Aug 17, 2020**

<b>1 Usage</b>	<b>3</b>
<b>2 User Guide</b>	<b>5</b>
2.1 Installation Guide . . . . .	5
2.2 Reduction Configuration . . . . .	6
2.3 Extraction Configuration . . . . .	7
2.4 LT SPRAT . . . . .	15
2.5 GMOS Longslit . . . . .	17
<b>3 Indices and tables</b>	<b>21</b>

This provides the spectroscopic data reduction for BHTOM. At the time of writing, it is planned for implementing the longslit spectral reduction of Gemini/GMOS, LT/SPRAT and LCO/Floyds.

# CHAPTER 1

---

## Usage

---

To perform a spectral extraction from SPRAT data, user only needs to type:

```
python sprat_extraction.py extraction_config.yaml
```

While for GMOS, the images have to be flattened first, before performing the spectral extraction:

```
python gmos_reduction.py reduction_config.yaml  
python gmos_extraction.py extraction_config.yaml
```

Some the Configuration Files section for more information.

## 2.1 Installation Guide

### 2.1.1 Dependencies

Python  $\geq$  3.6

These packages can be installed with pip

- numpy  $\geq$  1.16
- scipy  $\geq$  1.5
- spectres  $\geq$  2.1.1
- reportlab
- svglib
- pyyaml

These have to be installed from the respective development branches at

- <https://github.com/cylammarco/aspired#dev>
- <https://github.com/jveitchmichaelis/rascal#dev>

This is required if you wish to build the document locally

- <https://github.com/SuperKogito/sphinxcontrib-pdfembed>

### 2.1.2 BHTOM Spec

Clone the repository

```
git clone https://github.com/cylammarco/bhtomspec
git clone https://github.com/cylammarco/bhtomspec-example
```

To test the `bhtomspec`, all the examples should run, e.g.

```
python3 [some_path_a]/bhtomspec/SPRAT/sprat_extraction.py [some_path_b]/
↳bhtomspec-example/SPRAT/example/ExtractionCase1/20180810_lhs6328_case1.yaml
python3 [some_path_a]/bhtomspec/GMOS/gmos_reduction.py [some_path_b]/
↳bhtomspec-example/GMOS/example/ReductionCase1/flattening_config.yaml
python3 [some_path_a]/bhtomspec/GMOS/gmos_extraction.py [some_path_b]/
↳bhtomspec-example/GMOS/example/ExtractionCase1/extraction_config_1.yaml
```

There are 3 shell scripts that run all the examples, however, the path has to be configured before they work. For example, in `[some_path_b]/bhtomspec-example/SPRAT/run_all_examples.sh`

```
python3 sprat_extraction.py example/ExtractionCase1/20180810_lhs6328_case1.
↳yaml
python3 sprat_extraction.py example/ExtractionCase2/20180810_lhs6328_case2.
↳yaml
python3 sprat_extraction.py example/ExtractionCase3/20180810_lhs6328_case3.
↳yaml
python3 sprat_extraction.py example/ExtractionCase4/20180810_lhs6328_case4.
↳yaml
python3 sprat_extraction.py example/ExtractionCase5/20180810_lhs6328_case5.
↳yaml
```

has to be modified to

```
python3 [some_path_a]/bhtomspec/SPRAT/ssprat_extraction.py example/
↳ExtractionCase1/20180810_lhs6328_case1.yaml
python3 [some_path_a]/bhtomspec/SPRAT/ssprat_extraction.py example/
↳ExtractionCase2/20180810_lhs6328_case2.yaml
python3 [some_path_a]/bhtomspec/SPRAT/ssprat_extraction.py example/
↳ExtractionCase3/20180810_lhs6328_case3.yaml
python3 [some_path_a]/bhtomspec/SPRAT/ssprat_extraction.py example/
↳ExtractionCase4/20180810_lhs6328_case4.yaml
python3 [some_path_a]/bhtomspec/SPRAT/ssprat_extraction.py example/
↳ExtractionCase5/20180810_lhs6328_case5.yaml
```

before it can run.

### 2.1.3 Other repositories for BHTOM Spec

It is currently not a package, just scripts, so it is not registered on any package index service. It may happen if this project continues onto a full integration with BHTOM.

## 2.2 Reduction Configuration

This only applies to GMOS reduction where a full reduction is performed. SPRAT reductions begin with flattened spectral image data.

### 2.2.1 GMOS field-flattening configuration (YAML)

```
1 folder_path: "."
2 output_folder_path: "output"
```

(continues on next page)

(continued from previous page)

```

3 light_folder: ~
4 flat_folder: ~
5 arc_folder: ~
6 bias_folder: ~
7 arc_flat_folder: ~
8 arc_bias_folder: ~
9 light_extension: ["fits", "fit", "bz2", "gz"]
10 flat_extension: ["fits", "fit", "bz2", "gz"]
11 arc_extension: ["fits", "fit", "bz2", "gz"]
12 bias_extension: ["fits", "fit", "bz2", "gz"]
13 arc_flat_extension: ["fits", "fit", "bz2", "gz"]
14 arc_bias_extension: ["fits", "fit", "bz2", "gz"]
15 bias_master_filename: bias_master
16 arc_bias_master_filename: arc_bias_master
17 flat_row_size: 10
18 flat_edge_size: 10
19 flat_strip_size: 20
20 force_recreate_bias: false
21 save_bias: true
22 save_bias_format: ["fits", "numpy"]
23 overwrite_bias_image: true
24 save_flattened_image: true
25 save_flattened_image_format: ["fits", "numpy"]
26 overwrite_flattened_image: true
27 create_fig: true
28 show_fig: false
29 diagnostic_pdf: true

```

The *light\_folder*, *flat\_folder*, *arc\_folder*, *bias\_folder*, *arc\_flat\_folder* and *arc\_bias\_folder* are relative to the *folder\_path*. If they are empty, the folders are assumed to be called *light*, *flat*, *arc*, *bias*, *arc\_flat*, *arc\_bias* folders located at *folder\_path*.

All the files with the extension listed in the respective extension arguments (*light\_extension...*) will be processed.

*flat\_row\_size* is the number of rows on either size from the central row of the spectral image that are to be summed to compute the sensitivity function. *flat\_edge\_size* is the number of edge pixels that are removed in the computation. *flat\_strip\_size* is the number of pixels from the *flat\_edge\_size*-th pixel to be fitted a straight line over.

## 2.3 Extraction Configuration

This applies to both GMOS and SPRAT.

### 2.3.1 Extraction configuration (YAML)

Once the flattening is performed, the longslit spectral extraction is like any extractions from a generic spectrograph. The format of the parameter files for GMOS and SPRAT are the same. Most of the parameters can be kept constant, respective to the instrument. The file paths, which are the first few lines of the file, have to be updated for each extraction. The output data can be exported as FITS/CSV, static png/jpg/pdf image, an interactive plotly iframe, or just the JSON file for the plotly graph. The following shows the example YAML of the GMOS extraction.

```

1 folder_path: "."
2 output_folder_path: "20181115_gaia18cnz/output"
3

```

(continues on next page)

(continued from previous page)

```

4  # Input
5  science_file:
6    # - they have to be in a list
7    - "20181115_gaia18cnz/output/N20181115S0097_flattened.fits"
8    - "20181115_gaia18cnz/output/N20181115S0098_flattened.fits"
9    - "20181115_gaia18cnz/output/N20181115S0101_flattened.fits"
10   - "20181115_gaia18cnz/output/N20181115S0102_flattened.fits"
11  science_arc_file: "20181115_gaia18cnz/output/N20181115S0215_flattened.fits"
12
13  standard_file: "20180811_g191b2b/output/N20180811S0148_flattened.fits"
14  standard_arc_file: "20180811_g191b2b/output/N20180813S0115_flattened.fits"
15
16  # If sensitivity curve is provided, standard star extraction will be skipped
17  sensitivity_file: "20180811_g191b2b/output/sensitivity_itp.npy"
18
19  # Output - they have to be lists
20  science_output_file:
21    # - they have to be in a list
22    - "20181115_gaia18cnz/output/N20181115S0097"
23    - "20181115_gaia18cnz/output/N20181115S0098"
24    - "20181115_gaia18cnz/output/N20181115S0101"
25    - "20181115_gaia18cnz/output/N20181115S0102"
26  standard_output_file: "20180811_g191b2b/output/N20180811S0148"
27
28  science_output_type:
29    - "fits"
30    - "csv"
31    - "png"
32    - "iframe"
33  standard_output_type:
34    - "fits"
35    - "csv"
36    - "png"
37    - "iframe"
38
39  # Output
40  savefits: True
41  fits_output: 'flux_resampled+wavecal+flux+adu+adu_resampled'
42  fits_filename: 'reduced'
43  fits_stype: 'science'
44  fits_individual: False
45  fits_overwrite: False
46  savecsv: True
47  csv_output: 'flux_resampled+wavecal+flux+adu+adu_resampled'
48  csv_filename: 'reduced'
49  csv_stype: 'science'
50  csv_individual: False
51  csv_overwrite: False
52
53  # Only needed if images/iframe are being exported
54  width: 1920
55  height: 1080

```

It is then followed by all the extraction parameters. At the time of writing, the readnoise, gain, seeing and exptime are not read automatically from the header. In order to have a correct absolute flux calibration, the exposure time has to be filled in manually. The gain is constant for the instrument over time, so it does not need adjusting unless the observatory has changed the instrument setting. While the seeing varies with time, it does not affect the extraction quality, it can

slightly slow down the speed in aperture tracing, which is hardly a bottleneck process of the data extraction to begin with, so it can be left as it is. The same applies to the parameters for the standard.

```

1 # Science target
2
3 # TwoDSpec parameters

## 2.4 LT SPRAT

The Liverpool Telescope distributes the [SPRAT Level 2 \(L2\) data](#) in multi-extension FITS files containing a primary image array for the Level 1 (L1) reduced CCD frame and up to five FITS extensions of derived products. The executive summary of the data product is listed in the following table, full description can be referred to the same link above.

Table 1: Multi-extension FITS data format

Index	EXTNAME	Description
0	L1_IMAGE	Fieldflattened long-slit image.
1	LSS_NONSS	Wavelength calibrated and trimmed long-slit image.
2	SPEC_NONSS	Tophat extracted 1D spectrum.
3	SPEC_SS	Tophat extracted and sky subtracted 1D spectrum. Always exists if SPEC_NONSS exists, but it may not be picking the right regions for sky subtraction (e.g. nebulosity from the resolved host galaxy).
4	NORMFLUX	Detector response corrected SPEC_SS spectrum. Flux is normalised to unity over the region 5000-6000 Å. Always exists if SPEC_SS exists.
5	FLUX	Absolute flux calibrated spectrum in unit of $\text{erg} / \text{s} / \text{cm}^2 / \text{Å}$ .

The provided reduced data only guarantee to contain index 0 and 1. The native pipeline may fail to produce SPEC\_NONSS in crowded field; the flux may not be calibrated if the photometry from the acquisition image is not reliable (see [more here](#)).

### 2.4.1 With only the Science FITS file

If the data comes with 6 HDUs, the spectrum can be re-extracted directly from the LSS\_NONSS image, and then re-apply the absolute flux calibration by extracting the sensitivity function by dividing [SPEC\_SS] by [FLUX]. The sensitivity function the native pipeline applied is  $(\text{ADU} / \text{s}) / (\text{erg} / \text{s} / \text{cm}^2 / \text{Å})$ . This can improve the signal-to-noise ratio (SNR) by up to ~30% coming purely from the difference between optimal extraction and tophat extraction.

If the data comes with 5 HDUs, the same procedure applies except the absolute calibration will be done by using a pre-saved sensitivity function adjusted to the unit of  $(\text{erg} / \text{s} / \text{cm}^2 / \text{Å}) / \text{s}$ . This will only give the estimate of the

absolute flux. The spectral shape will be the same as the NORMFLUX data from their native pipeline.

If the data comes with less than 5 HDUs, the sensitivity function will be taken from the pre-saved data, which can be out of date but should give a good general shape of the spectrum.

## 2.4.2 With only the Science and Standard FITS file

It is not common for the LT programmes to include standard frames. However, if one is provided, it can be used to compute a more representative response function. The procedures are the same as above in terms of spectral extraction. The sensitivity will be computed by providing the name of the standard star in the configuration file.

## 2.4.3 With arc files

The arc file is taken every time after an observing group/block. It is extremely rare that the automated LT pipeline fail to perform wavelength calibration. Using a different way to compute the wavelength solution with more lines with RASCAL, a recalibration may give a marginal improvement in the calibration (less than the resolution in any case). We recommend providing an arc file if you wish to use the native pixel scale such that the resampling done from L1\_IMAGE to LSS\_NONSS will not lead to any loss of information, regardless of how small they can be.

## 2.4.4 Data Processing

The above processes will be assigned as one of the following five scenarios when handled by this pipeline:

1. science frame only (Science L1 Image)
    - i. Improving the S/N ratio by using optimal extraction (Science)
  2. science + science arc frames only (Science LSS\_NONSS)
    - i. Improving the S/N ratio by using optimal extraction (Science)
    - ii. Recomputing the wavelength solution (Science)
  3. science + standard frames only (Science L1 Image + Standard L1 Image)
    - i. Improving the S/N ratio by using optimal extraction (Science + Standard)
    - ii. Recompute the sensitivity response function
  4. science + science arc + standard frames (Science L1 Image + Standard LSS\_NONSS)
    - i. Improving the S/N ratio by using optimal extraction (Science + Standard)
    - ii. Recomputing the wavelength solution (Science)
    - iii. Recompute the sensitivity response function
  5. science + science arc + standard + standard arc frames (Science L1 Image + Standard L1 Image)
    - i. Improving the S/N ratio by using optimal extraction (Science + Standard)
    - ii. Recomputing the wavelength solution (Science + Standard)
    - iii. Recompute the sensitivity response function
- science + standard + standard arc will be treated as (3)
  - science + standard arc will be treated as (1)
  - If sensitivity file is provided, they will be used and the reprocessing will ignore the standard and standard arc files, i.e. (3) will reduced to (1), (4) & (5) will reduced to (2).

## 2.5 GMOS Longslit

The GMOS Longslit spectrograph is available with both Gemini North and Gemini South. The characteristics of the instruments are very similar, with only some minute differences, at the detector plane. This comment is at least true for the purpose of this quicklook pipeline. The non-negligible differences are taken care of, for example, different sizes of the chip gaps. [See the detailed description of the instruments here.](#)

This quicklook pipeline divides the reduction in two parts - (1) fieldflattening and (2) spectral extraction. The first part takes care of the different binnings, Region Of Interest (ROI), chip gap sizes (North/South are different), bias subtraction, overscan subtraction and response function within chip & across the focal plane. The second part is the spectral extraction.

### 2.5.1 1. Fieldflattening

The procedure follows that described on the [US National Gemini Office GMOS cookbook page](#). The *gmos\_spectral\_extraction.py* keeps the functions for performing image reconstruction, generating master bias and global sensitivity function. The only procedure that is not directly obvious from the page is the construction of the response function across the detector array, the steps are as follow:

1. Generate the master flat by dividing the stacked flat by the mean (with sigma clipping and NAN handled).
2. Sum the ADU counts over the few pixels covered by the 2D spectrum in the spatial direction to generate the relative response across the spectral direction.
3. Fit straight lines through the back-to-back end pixels (ignore the last few pixels) of the relative response between the adjacent chips in order to normalise the inter-chip response. See the *linear\_fit()* function.
4. Apply the global response function to absolutely normalise the 3-chip image.

In order to reduce the images, the *gmos\_reduction.py* should be executed, which makes use of the *gmos\_extraction.py* and the parameter YAML file.

The different combinations of available frames will be assigned as one of the following eight scenarios, we require at least one light and one flat frame:

1. Light + Flat
2. Light + Flat + Bias
3. Light + Flat + Arc
4. Light + Flat + Arc + Arc Flat
5. Light + Flat + Arc + Arc Bias
6. Light + Flat + Bias + Arc + Arc Flat
7. Light + Flat + Bias + Arc + Arc Bias
8. Light + Flat + Bias + Arc + Arc Flat + Arc Bias

An example diagnostic pdf:

### 2.5.2 2. Spectral Extraction

After the images are flattened and reconstructed, the '*gmos\_spectral\_extraction.py*' can be executed with another YAML parameter file for the spectral extraction configuration. For the purposes of quicklook, most of the parameters can be kept untouched. The paths have to be changed accordingly in order to extract the spectra properly. Mismatched binnings could be handled by automatically up/downsampling the flat/bias frames. However, even when mismatched

instruments (North/South) and mismatched gratings can allow the output of a reduced spectrum, the pipeline is not checking all the cases whether the input combination makes sense.

### **With only Science FITS file**

Extraction will be performed and only the ADU as a function of pixel can be produced.

### **With only Science and Arc FITS files**

Extraction will be performed and only the ADU as a function of wavelength can be produced.

### **With only Science, Standard and one of Science or Standard Arc FITS files**

Extraction will be performed on both the science and standard spectra. The arc will be used for wavelength calibration for both frames. Wavelength and flux will be calibrated.

### **With Science, Science Arc, Standard and Standard Arc FITS file**

Extraction will be performed on both the science and standard spectra. The respective arc will be used for wavelength calibration for the respective frames. Wavelength and flux will be calibrated.

The different combinations of available frames from the fieldflattening will give different sets of final products, they will be one of the following five scenarios:

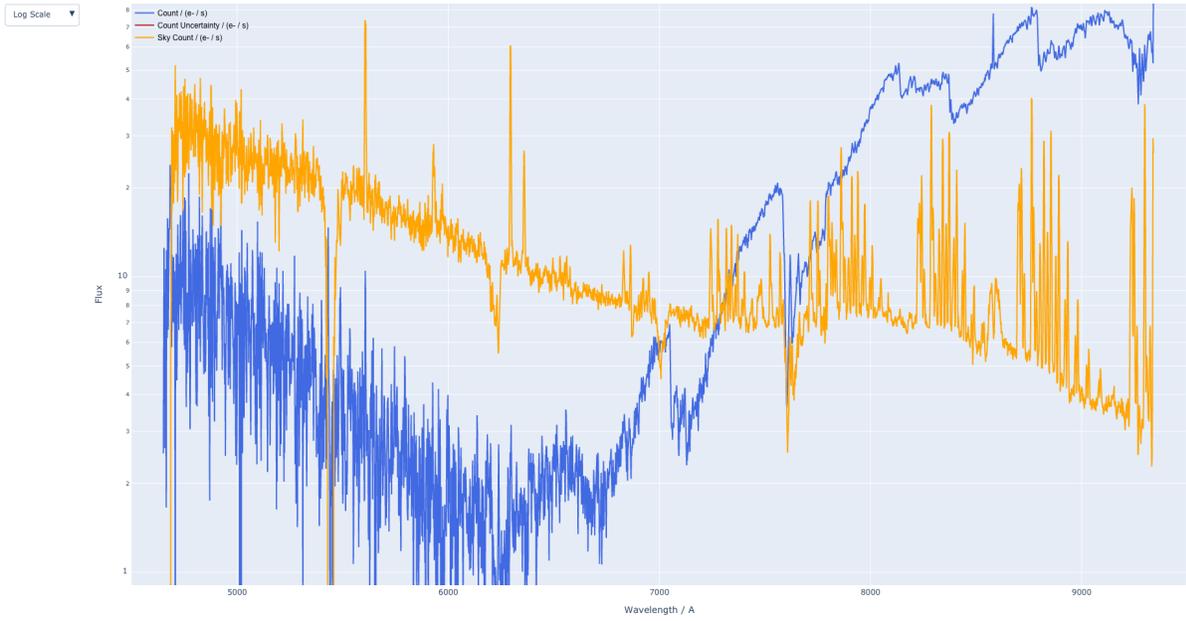

Table 2: Data Product

Case	Input	Output
1	Science	ADU(pixel)
2	Science + Arc	ADU(wavelength)
3	Science + Arc + Sensitivity Curve	Flux(wavelength) from pre-saved sensitivity curve, though it may not provide a good SED, it should be good enough for quick inspection. Need to be careful to select the right combination of grating and central wavelength.
4	Science + Arc + Standard	Flux(wavelength) with the potential in getting better absolute flux calibration, if a bad standard is used, the quality will be lower than (3)
5	Science + Arc + Standard + Standard Arc	Flux(wavelength) with the potential in getting better absolute flux calibration, if a bad standard is used, the quality will be lower than (3)

- If sensitivity file is provided, (4) & (5) will reduced to (3).
- Without Arc, sensitivity file cannot be used, it will remain as case (1).

An example output html of the extracted spectrum (click for the interactive display in a new tab):
